Q: How to detect change in state when using Material UI Switch component? How can I listen to changes in the state of the switch component? The docs do not specify a way to do this. I can use a callback and setState, but that would require me to pass the callback. I assume the component is simply using one of these utils internally and doesn't expose it to anyone. A: It's not exposed. You could use componentWillReceiveProps: componentWillReceiveProps(nextProps) { if (this.props.checked!== nextProps.checked) { // the checkbox has changed, you could do something here } } Hope it helps! Q: Decoding elements of tag in XML I have some bad XML: value another value yet another value value another value yet another value value another value yet another value How can I decode it in Python, to get to the elements of the tags in the second level using BeautifulSoup? I got all the data I need but no access to the elements of the tags. I had to use a python library xml_etree.ElementTree. Can someone help me with this? A: Assuming you want to get the fields out of an entity node, this should do the job: from bs4 import BeautifulSoup xml = '

What's New In?

In an ever-increasing market for information and other data communications, users and customers seek to obtain data and information more quickly. However, when data and information must be transmitted through a network, each segment of the network becomes a potential transmission point or bottleneck. To minimize the number of transmission points needed, an increasing trend is to transmit the data and information by way of a plurality of links, all passing through a central hub, before the data is distributed throughout the network. These links are normally dedicated as circuit switched links. More recently, the need to protect the data against malicious or accidental loss has generated an interest in developing a data transmission protocol that would allow communications to take place between two or more hubs by way of a packet switched network. The protocol takes advantage of two or more hubs on the network connected to an Internet Protocol (IP) switch via a single transmission media (normally a link) that transmits an IP packet between two nodes on the network. Conventional single media networks treat all transmissions through the network using the same priority. While this may be reasonable in some environments, a situation may arise where a higher priority transmission is being delayed longer than a lower priority transmission. If a data loss can occur in the higher priority transmission, a subsequent failure in the lower priority transmission should cause the data to be retransmitted and the network to re-assemble the data. However, the data transmitted between two adjacent hubs is not capable of being transmitted between two non-adjacent hubs because the data is often being transmitted through a different path. Accordingly, single network data networks have not been successful in providing data communications between a plurality of different hubs. The present invention, therefore, provides a method and apparatus for transmitting data between nodes in a two-tier network that transmits data packets between two or more networks using a single transmission medium. The invention allows data and information to be transmitted through a single link that can be simultaneously utilized to communicate with several hubs connected to the single link. The single link communicates using an Internet Protocol that transmits packets of data, addressing information, headers, or other types of data packets. Thus, if a failure occurs at one hub, a packet is not required to be retransmitted through the entire network. Instead, the packets can be transmitted through the single link that is shared by several hubs, since this link is always available. An advantage of the present invention is that data and information are transmitted through an IP switched network such that the transmitted data and information is shared between nodes. Accordingly,
