16 and lower (on windows 7, 8, 8.1 and 10) A: Generally you can tell if the file is ASCII text by checking if the first 4 bytes contain a string of the form (bytes) "----- " (and the filename separator " " is between the two quotes). In contrast to most programming languages, the various emojis in Unicode are included right in the file as well. Unfortunately, TET character data in Unicode encodes as multiple bytes. E.g. in UTF-8 there's a sequence of (byte) 0x2B,0x2F,0x31,0x38,0x49,0x4F,0x53. If it doesn't have any full-width Unicode characters like "ψ" it can be disassembled into TET when encoded as UTF-8, but this is a very rare case. If you want to separate emojis from other Unicode codepoints you'll have to use a byte-wise text processing tool. "sed -c './!s/./g'" might work. Anyway, a generic Unicode decoder can be found here (they seem to use a slightly different encoding). And maybe a letter gets converted into a number and that's why it's not displayed correctly. A: An obvious way to do it is to convert the file into a multi-byte standard, such as UTF-16. Then you just have to do: scanf("%0x", &u16[offset]); If the characters are valid according to the standard, you'll get a correct value. If they're not, you'll get a negative value. If they are, you'll get a positive value. The reason this works is that a string in UTF-16 begins with a two-byte sequence with the values 0xFE and 0xFF. So, by parsing these two bytes, you know that the next 2 bytes must be the start of the Unicode character, which is what we're interested in. Shipping Shipping We do all of our packaging and shipping in small batches to reduce the environmental impact. We use sustainable and responsibly sourced packaging materials such as recycled cardboard and reusable bubble wrap or Mylar. We ship to the United States via US Postal Service and all orders are shipped within 48 hours after the payment is received
